therapy has had a rocky history. The first reports on DNA methylation changes in cancer described global loss of methylation, which has been suggested to drive tumorigenesis through activation of oncogenic proteins or induction of chromosomal instability. In this context, reducing DNA methylation was viewed

Abstract. DNA

initiation and  
progression. Moreover,  
cancer cells seem to  
depend upon these  
aberrant DNA  
methylation profiles to  
thrive. Finally, DNA  
methylation  
modifications are  
reversible, highlighting  
the potential to target  
the global methylation  
patterns for cancer  
therapy.

Information on DNA methylation in the normal colonic tissues was available on 234 colon cancer patients (164 never/ex-HT users and 70 current HT users; Table IV). On the
